Executive Summary

Stock

This assessment reports the status of the Petrale sole (*Eopsetta jordani*) off U.S. coast of California, Oregon, and Washington using data through 2018. While petrale sole are modeled as a single stock, the spatial aspects of the coast-wide population are addressed through geographic separation of data sources/fleets where possible. There is currently no genetic evidence suggesting distinct biological stocks of petrale sole off the U.S. coast. The limited tagging data available to describe adult movement suggests that petrale sole may have some homing ability for deep water spawning sites but also have the ability to move long distances between spawning sites, inter-spawning season, as well as seasonally.

Landings

While records do not exist, the earliest catches of Petrale sole are reported in 1876 in California and 1884 in Oregon. In this assessment, fishery removals have been divided among 4 fleets: 1) winter North trawl, 2) summer North trawl, 3) winter South trawl, and 4) summer South trawl. Landings for the North fleet are defined as fish landed in Washington and Oregon ports. Landings for the South fleet are defined as fish landed in California ports. Recent annual catches during 1981-2014 range between 749-2,903 mt (Table XX, Figure XX). Petrale sole are caught nearly exclusively by trawl fleets; non-trawl gears contribute less than 3% of the catches. Based on the 2005 assessment, annual catch limits (ACLs) were reduced to 2499 mt for 2007-2008. Following the 2009 assessment ACLs were further reduced to a low of 976 mt for 2011 and have subsequently increased to a high value of 3,136 for 2017. From the inception of the fishery through the war years, the vast majority of catches occurred between March and October (the summer fishery), when the stock is dispersed over the continental shelf. The post-World War II period witnessed a steady decline in the amount and proportion of annual catches occurring during the summer months (March-October). Conversely, Petrale sole catch during the winter season (November-February), when the fishery targets spawning aggregations, has exhibited a steadily increasing trend since the 1940s. From the mid-1980s through the early 2000s, catches during the winter months were roughly equivalent to or exceeded catches throughout the remainder of the year, whereas during the past 10 years the relative catches during the winter and summer have been more variable across years (Figure XX). Petrale sole are a desirable market species and discarding has historically been low.

Table a: Landings (mt) for the past 10 years for Petrale sole by source.

| Year | Winter | Summer | Winter | Summer | Total |
|------|--------|---------|--------|--------|----------|
| | (N) | (N) | (S) | (S) | Landings |
| 2009 | 846.71 | 641.75 | 469.66 | 250.38 | 2208.49 |

Figure a: Landings of Petrale sole by the Northern and Southern winter and summer fleets of the US west coast.

Data and Assessment

This an update assessment for Petrale sole, which was last assessed in 2013 and updated in 2015. The update assessment was conducted using the length- and age-structured modeling software Stock Synthesis (version 3.30.03.XX). The coastwide population was modeled allowing separate growth and mortality parameters for each sex (a two-sex model) with the fishing year beginning on November 1 and ending on October 31. The fisheries are structured seasonally based on winter (November to February) and summer (March to October) fishing seasons due to the development and growth of the wintertime fishery, which began in the 1950s. In recent decades wintertime catches have often exceed summertime catches. The fisheries modeled as the North Winter and North Summer, where the north includes both Washington and Oregon, and South Winter and South Summer encompasses California fisheries.

The model includes catch, length- and age-frequency data from the trawl fleets as well as standardized winter fishery catch-per-unit-effort (CPUE) indices. Biological data are derived from both port and on-board observer sampling programs. The National Marine Fisheries Service (NMFS) early (1980, 1983, 1986, 1989, 1992) and late (1995, 1998, 2001, and 2004) Triennial bottom trawl survey and the Northwest Fisheries Science Center (NWFSC) trawl survey (2003-2018) relative biomass indices and biological sampling provide fishery independent information on relative trend and demographics of the Petrale sole stock.

Updated Data

The base stock assessment model structure is consistent with the 2013 assessment and the 2015 update, except as noted here. Additions to the model include 1) landings data for 2015 - 2018, 2) commercial composition data (age and length) for 2015 - 2018, 3) NWFSC groundfish trawl survey index for 2015 - 2018, and 4) age and length composition data from the NWFSC groundfish trawl survey.

Modifications from the previous assessment model include:

- 1. Survey indices were calculated using VAST.
- 2. Length-weight relationship parameters estimated outside of the stock assessment model from the NWFSC groundfish trawl survey data up to 2018 and input as fixed values.
- 3. Early commercial age data for OR and WA were not combined, consistent with the 2011 assessment.
- 4. Fitting using SS v.3.30.XX.
- 5. Model tuning to re-weight data.

Stock Biomass

| 2015 | 0.006 | 0.004 - 0.008 | 0.001 | 0.000 - 0.001 |
| 2016 | 0.005 | 0.004 - 0.007 | 0.000 | 0.000 - 0.001 |
| 2017 | 0.005 | 0.003 - 0.006 | 0.000 | 0.000 - 0.000 |
| 2018 | 0.004 | 0.003 - 0.005 | 0.000 | 0.000 - 0.000 |

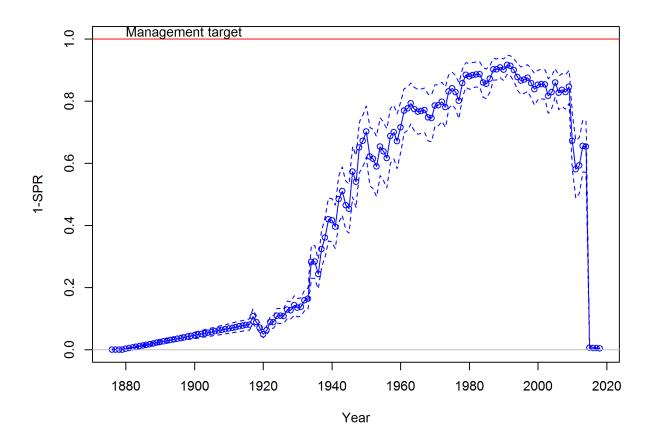

Figure e: Estimated relative spawning potential ratio (1-SPR)/(1-SPR30%) for the base model. One minus SPR is plotted so that higher exploitation rates occur on the upper portion of the y-axis. The management target is plotted as a red horizontal line and values above this reflect harvests in excess of the overfishing proxy based on the SPR30% harvest rate. The last year in the time-series is 2018.

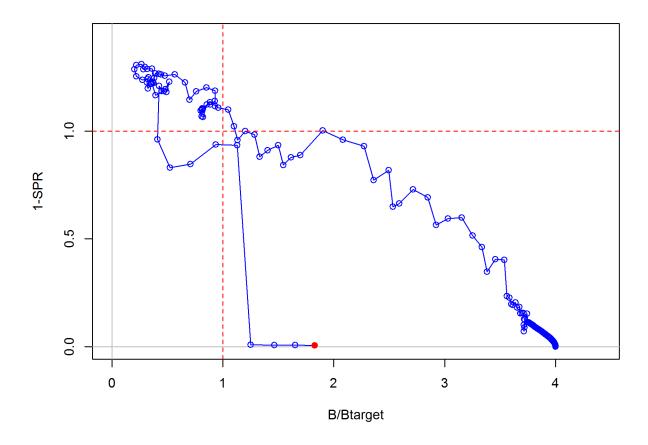

Figure f: Phase plot of estimated (1-SPR)/(1-SPR30%) vs. depletion (B/Btarget) for the base case model. The red circle indicates 2018 estimated status and exploitation for Petrale sole.

Ecosystem Considerations

Reference Points

This stock assessment estimates that the spawning output of Petrale sole is above the management target. Due to reduced landing and the large 2008 year-class, an increasing trend in spawning output was estimated in the base model. The estimated depletion in 2019 is 50.0% ($\sim 95\%$ asymptotic interval: $\pm 38.8\%$ -61.2%), corresponding to an unfished spawning output of 16,841 mt ($\sim 95\%$ asymptotic interval: 13,924-19,758 mt). Unfished age 3+ biomass was estimated to be 53,873.7 mt in the base model. The target spawning output based on the biomass target ($SB_{25\%}$) is 8,423.3 mt, with an equilibrium catch of 2,729.5 mt. Equilibrium yield at the proxy F_{MSY} harvest rate corresponding to $SPR_{30\%}$ is 2,702.4 mt. Estimated MSY catch is at a 2,742.2 spawning output of 7,323.1 mt (21.7% depletion)

Table h: Decision table summary of 10-year projections beginning in 2021 for alternate states of nature based on an axis of uncertainty for the base model. The removals in 2019 and 2020 were set at the defined management specification of XXX mt for each year assuming full attainment. The range of natural mortality values corresponded to the 12.5 and 87.5th quantile from the uncertainty around final spawning biomass. Columns range over low, mid, and high states of nature, and rows range over different assumptions of catch levels. The SPR50 catch stream is based on the equilibrium yield applying the SPR50 harvest rate.

Research and Data Needs

There are many areas of research that could be undertaken to benefit the understanding and assessment of Petrale sole. Below, are issues that are considered of importance.

- 1. Natural mortality:
- 2. Steepness:
- 3. Basin-wide understanding of stock structure, biology, connectivity, and distribution:

Table i: Base model results summary.

1 Introduction

- 1.1 Distribution and Stock Structure
- 1.2 Historical and Current Fishery
- 1.3 Summary of Management History and Performance
- 1.4 Fisheries off Canada and Alaska

2 Data

Data used in the Petrale sole assessment are summarized in Figure 2. A description of each data source is provided below.

2.1 Fishery-Independent Data

- 2.1.1 Northwest Fisheries Science Center (NWFSC) Shelf-Slope Survey
- 2.1.2 Northwest Fisheries Science Center (NWFSC) Slope Survey

2.1.3 Triennial Shelf Survey

The Triennial shelf survey was first conducted by the AFSC in 1977 and spanned the time-frame from 1977-2004. The survey's design and sampling methods are most recently described in Weinberg et al. (2002). Its basic design was a series of equally-spaced transects from which searches for tows in a specific depth range were initiated. The survey design has changed slightly over the period of time. In general, all of the surveys were conducted in the mid-summer through early fall: the 1977 survey was conducted from early July through late September; the surveys from 1980 through 1989 ran from mid-July to late September; the 1992 survey spanned from mid-July through early October; the 1995 survey was conducted from early June to late August; the 1998 survey ran from early June through early August; and the 2001 and 2004 surveys were conducted in May-July.

Haul depths ranged from 91-457 m during the 1977 survey with no hauls shallower than 91 m. The surveys in 1980, 1983, and 1986 covered the West Coast south to 36.8° N latitude and a

depth range of 55-366 m. The surveys in 1989 and 1992 covered the same depth range but extended the southern range to 34.5° N (near Point Conception). From 1995 through 2004, the surveys covered the depth range 55-500 m and surveyed south to 34.5° N. In the final year of the Triennial series, 2004, the NWFSC's Fishery Resource and Monitoring division (FRAM) conducted the survey and followed very similar protocols as the AFSC.

Although the Triennial shelf survey was used in the 2011 assessment, it was not used in the final base model for the current assessment for a number of reasons. First, there were concerns regarding the varying sampling and targeting of specific species by year across the time-series. Secondly, the Triennial shelf survey targeted the shelf of the West Coast and would not be expected to sample well slope species such as Petrale sole. There were limited observations of Petrale sole relative to other surveys (e.g. NWFSC shelf-slope survey) and the length and age distributions varied in such a manner that would indicate either poor sampling of Petrale sole or inconsistent sampling of the population.

2.2 Fishery-Dependent Data

2.2.1 Commercial Fishery Landings

Washington

Oregon

California

2.2.2 Discards

Data on discards of Petrale sole are available from two different data sources. The earliest source is referred to as the Pikitch data and comes from a study organized by Ellen Pikitch that collected trawl discards from 1985-1987 (Pikitch et al. 1988). The northern and southern boundaries of the study were 48°42′ N latitude and 42°60′ N latitude respectively, which is primarily within the Columbia INPFC area (Pikitch et al. 1988, Rogers and Pikitch 1992). Participation in the study was voluntary and included vessels using bottom, midwater, and shrimp trawl gears. Observers of normal fishing operations on commercial vessels collected the data, estimated the total weight of the catch by tow, and recorded the weight of species retained and discarded in the sample. Results of the Pikitch data were obtained from John Wallace (personal communication, NWFSC, NOAA) in the form of ratios of discard weight to retained weight of Petrale sole and sex-specific length frequencies. Discard estimates are shown in Table 9.

The second source is from the West Coast Groundfish Observer Program (WCGOP). This program is part of the NWFSC and has been recording discard observations since 2003.

Table 9 shows the discard ratios (discarded/(discarded + retained)) of Petrale sole from WCGOP. Since 2011, when the trawl rationalization program was implemented, observer coverage rates increased to nearly 100% for all the limited entry trawl vessels in the program and discard rates declined compared to pre-2011 rates. Discard rates were obtained for both the catch-share and the non-catch share sector for Petrale sole. A single discard rate was calculated by weighting discard rates based on the commercial landings by each sector. Coefficient of variations were calculated for the non-catch shares sector and pre-catch share years by bootstrapping vessels within ports because the observer program randomly chooses vessels within ports to be observed. Post-ITQ, all catch-share vessels have 100% observer coverage and discarding is assumed to be known.

2.2.3 Fishery Length and Age Data

2.2.3.1 Commercial Fishery

Input effN =
$$N_{\text{trips}} + 0.138 * N_{\text{fish}}$$
 if $N_{\text{fish}}/N_{\text{trips}}$ is < 44
Input effN = $7.06 * N_{\text{trips}}$ if $N_{\text{fish}}/N_{\text{trips}}$ is ≥ 44

2.2.4 Historical Commercial Catch-Per-Unit Effort

2.3 Biological Data

- 2.3.1 Natural Mortality
- 2.3.2 Sex Ratio, Maturation, and Fecundity
- 2.3.3 Length-Weight Relationship
- 2.3.4 Growth (Length-at-Age)
- 2.3.5 Ageing Precision and Bias
- 2.4 History of Modeling Approaches Used for This Stock
- 2.4.1 Previous Assessments

3 Assessment

3.1 General Model Specifications and Assumptions

Stock Synthesis version 3.30.03.XX was used to estimate the parameters in the model. R4SS, version 1.XX.X, along with R version 3.3.2 were used to investigate and plot model fits. A summary of the data sources used in the model (details discussed above) is shown in Figure 2.

- 3.1.1 Changes Between the 2015 Update Assessment Model and Current Model
- 3.1.2 Summary of Fleets and Areas
- 3.1.3 Other Specifications
- 3.1.4 Modeling Software

The STAT team used Stock Synthesis version 3.30.03.XX developed by Dr. Richard Methot at the NWFSC (Methot and Wetzel 2013). This most recent version was used because it

included improvements and corrections to older versions.

| 2028 | 3712 | 3389 | 5084 | 73.8 |

Table 30: Decision table summary of 10-year projections beginning in 2021 for alternate states of nature based on an axis of uncertainty for the base model. The removals in 2017 and 2018 were set at the defined management specification of 281 mt for each year assuming full attainment. Columns range over low, mid, and high states of nature over natural mortality, and rows range over different assumptions of catch levels. An entry of "—" indicates that the stock is driven to very low abundance under the particular scenario.

| | | | States of nature | | | | | | |

9 Figures

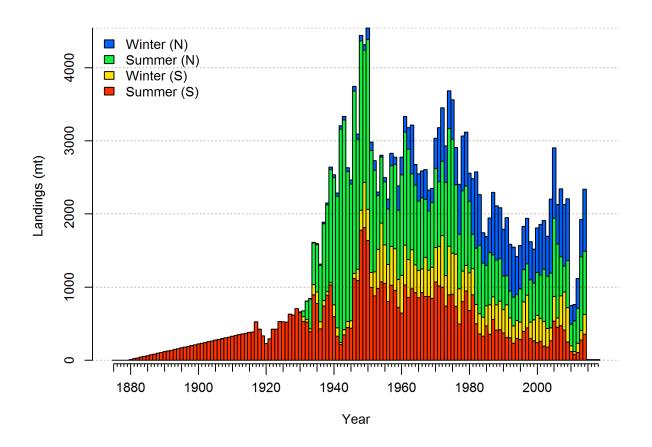

Figure 1: Total catches Petrale sole through 2016.

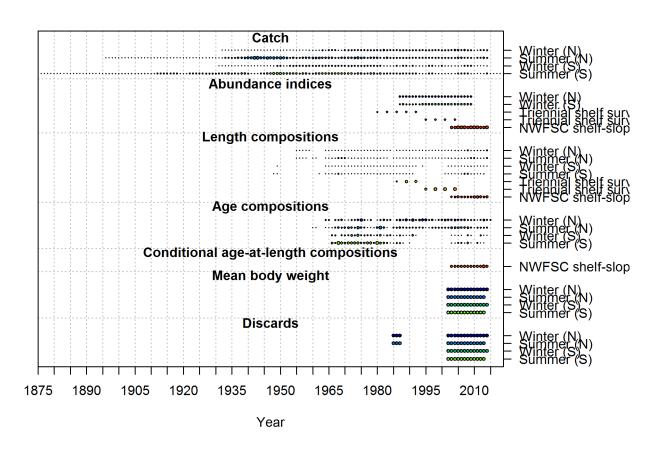

Figure 2: Summary of data sources used in the base model.

Ending year expected growth (with 95% intervals)

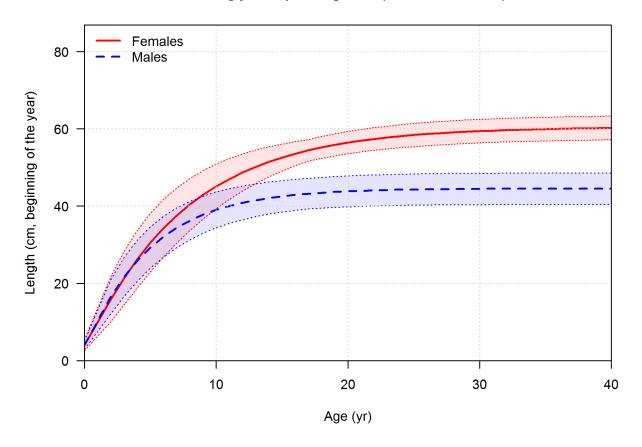

Figure 3: Estimated length-at-age for male and female for Petrale sole with estimated CV.

Age-0 recruits (1,000s) with ~95% asymptotic intervals

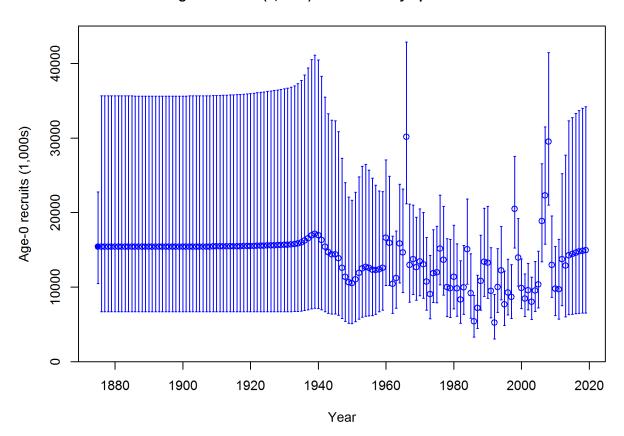

Figure 4: Estimated time-series of recruitment for Petrale sole.

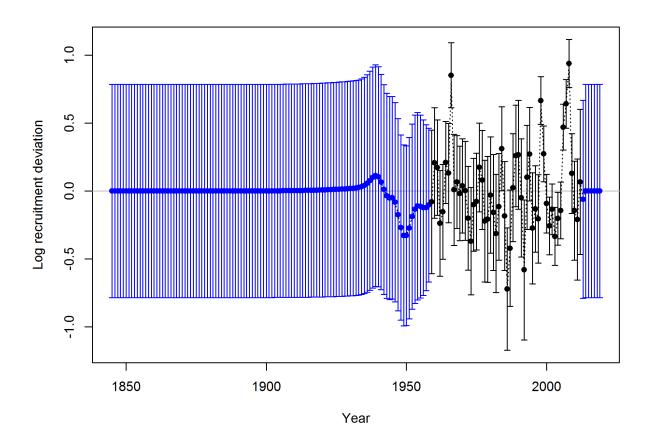

Figure 5: Estimated time-series of recruitment deviations for Petrale sole.

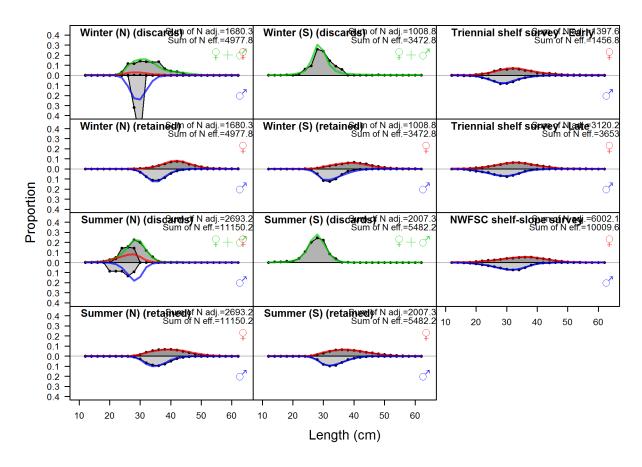

Figure 6: Length compositions aggregated across time by fleet. Labels 'retained' and 'discard' indicate retained or discarded samples for each fleet. Panels without this designation represent the whole catch. The Triennial shelf survey length data were not used in the final model, but the implied model fits are shown.

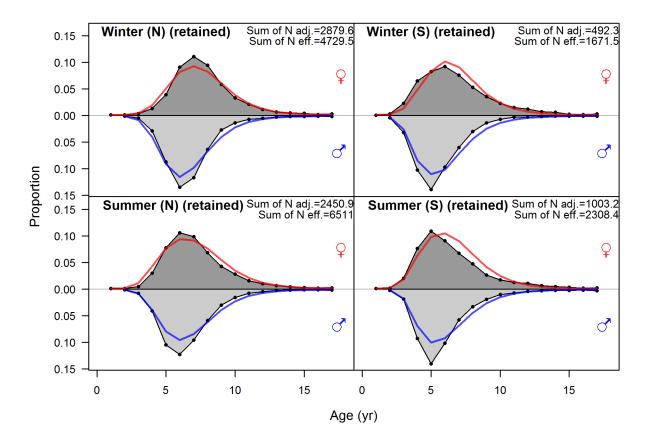

Figure 7: Age compositions aggregated across time by fleet. The Triennial shelf survey age data were not used in the final model, but the implied model fits are shown.

Spawning biomass (mt) with ~95% asymptotic intervals

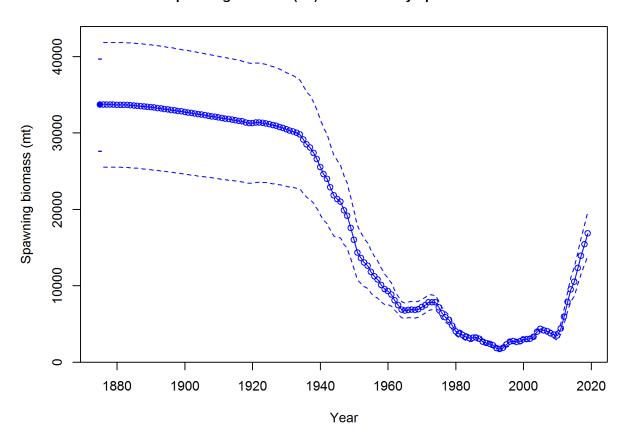

Figure 8: Estimated time-series of spawning output trajectory (circles and line: median; light broken lines: 95% credibility intervals) for Petrale sole.

Total biomass (mt) 1880 1900 1920 1940 1960 1980 2000 2020

Total biomass (mt)

Figure 9: Estimated time-series of total biomass for Petrale sole.

Year

Spawning depletion with ~95% asymptotic intervals

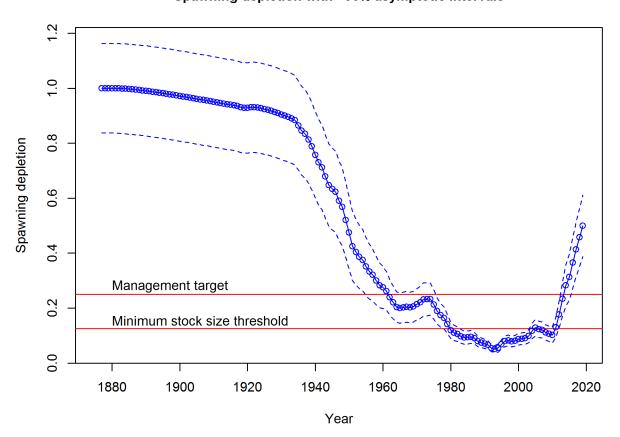

Figure 10: Estimated time-series of relative spawning output (depletion) (circles and line: median; light broken lines: 95% credibility intervals) for Petrale sole.

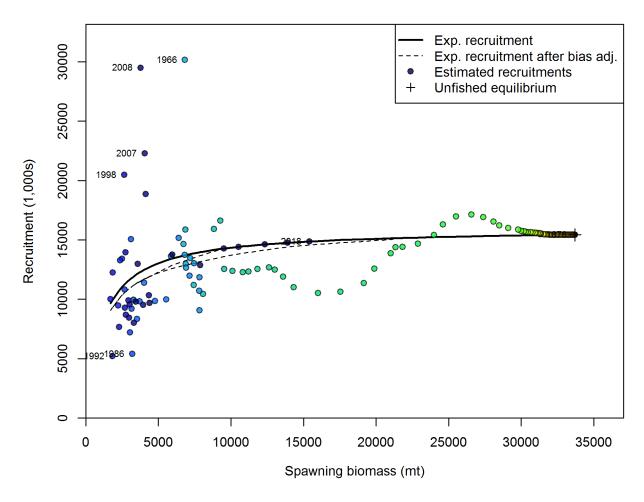

Figure 11: Estimated recruitment (red circles) and the assumed stock-recruit relationship (black line). The green line shows the effect of the bias correction for the lognormal distribution

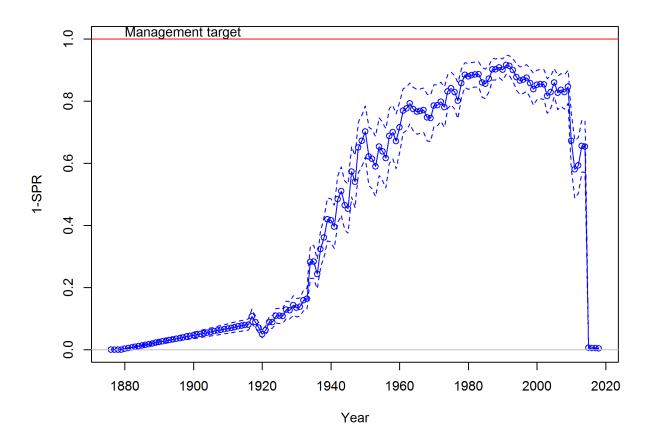

Figure 12: Estimated spawning potential ratio (1-SPR)/(1-SPR30%) for the base-case model. One minus SPR is plotted so that higher exploitation rates occur on the upper portion of the y-axis. The management target is plotted as a red horizontal line and values above this reflect harvests in excess of the overfishing proxy based on the SPR30% harvest rate. The last year in the time series is 2018.

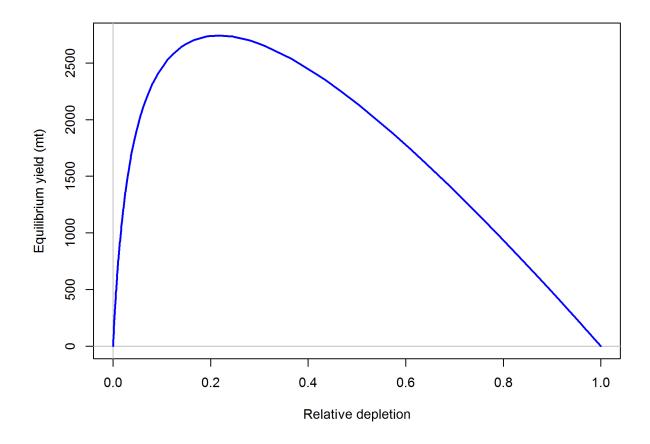

Figure 13: Equilibrium yield curve for the base case model. Values are based on the 2018 fishery selectivity and with steepness fixed at 0.89.
